Chapter 1: Installing and Configuring OS-9®

This chapter describes installing and configuring OS-9® on the Hitachi HS8001 board. It includes the following sections:

- Development Environment Overview
- Requirements and Compatibility
- Connecting the Target to the Host
- Building the OS-9 ROM Image
- Transferring the ROM Image to the Target
- Optional Procedures
Development Environment Overview

Figure 1-1 shows a typical development environment for the Hitachi HS8001 board. The following illustration shows the minimum equipment required for software development using OS-9 on the HS8001 board.

Figure 1-1 Hitachi HS8001 Development Environment
Requirements and Compatibility

Note
Before you begin, install the Microwave OS-9 for MIPS CD-ROM on your host PC.

Host Hardware Requirements (PC Compatible)
Your host PC must have the following minimum hardware characteristics:
- 32MB of RAM
- an Ethernet network card

Host Software Requirements (PC Compatible)
Your host PC must have the following software installed:
- Windows 95, 98, ME, 2000, or NT

Target Hardware Requirements
Your MIPS evaluation board requires the following hardware:
- a power supply
- an RS-232 null modem serial cable (for serial console)
- an Ethernet cable or a second RS-232 null modem serial cable (for downloading programs to the board)
Connecting the Target to the Host

Connecting the Hitachi HS8001 to your host PC involves attaching cables to the reference board, configuring switch settings for the Hitachi Debug Monitor, and booting the target. Once you have done these tasks, you can use the serial console in Hawk™ to verify the serial connection.

Attaching the Cables

Complete the following steps to attach the cables to the reference board:

- **Step 1.** Attach the power cable to the connector on the board (CN5).
- **Step 2.** Connect a Null Modem cable to the Debug Serial Port. This serial port is the one closest to the PS/2 and RJ-45 Ethernet connector.
- **Step 3.** Connect the other end of the Null Modem cable to COM1 on your host machine.

Configuring Switches for the Hitachi Debug Monitor

Before powering on the target, you will need to configure switches for the Hitachi Debug Monitor. The Hitachi Debug Monitor is the program that will be used to download the OS-9 image into RAM.

In order to use the Debug Monitor as required, you will need to configure the switches for use with OS-9. Most of the factory switch settings for the Hitachi Debug Monitor are appropriate for configuring OS-9. However, you will need to verify that the following switches are set as indicated:
Note
The switches listed below are labeled both in Figure 1-1 and on your HS8001 board.

- Set SW10 and SW11 to 1.
- Set SW27 and SW28 to 0.
- Set SW15 and SW16 to 0.

For More Information
For more information regarding switch settings for Hitachi HS8001 board, refer to the CPU Board User’s Guide, included with your hardware.

Boot to the Hitachi Debug Monitor

Once you have attached the appropriate cables and configured the switch settings for the Hitachi Debug Monitor, you can safely power on the HS8001 board and boot to the Debug Monitor. To do this, complete the following steps:

Step 1. From your host machine, access and open your Hyperterminal program.
Step 2. Once Hyperterminal is open, establish a new connection by selecting New Connection from the File menu.
Step 3. Select a name for your connection and click OK.
Step 4. From the Connet To dialog, select the appropriate COM port for your connection and click OK.
Step 5. Under the Port Settings dialog, apply the following settings:
Step 6. Apply power to the HS8001 board. You should now see a screen appear on your host PC for the Hitachi Debug Monitor. It should look similar to the following example:

SH8000 CPU BOARD Debug Monitor V0.96-B 010702
Boot from DDR Memory           WS1.2 Release

Building the OS-9 ROM Image

The OS-9 ROM Image is a set of files and modules that collectively make up the OS-9 operating system. The specific ROM Image contents can vary from system to system depending on hardware capabilities and user requirements.

To simplify the process of loading and testing OS-9, the ROM Image is generally divided into two parts—the low-level image, called coreboot; and the high-level image, called bootfile.

Coreboot

The coreboot image is generally responsible for initializing hardware devices and locating the high-level (or bootfile) image as specified by its configuration. For example from a FLASH part or Ethernet network. It is also responsible for building basic structures based on the image it finds and passing control to the kernel to bring up the OS-9 system.

Bootfile

The bootfile image contains the kernel and other high-level modules (initialization module, file managers, drivers, descriptors, applications). The image is loaded into memory based on the device you select from the boot menu. The bootfile image normally brings up an OS-9 shell prompt, but can be configured to automatically start an application.

Microware provides a Configuration Wizard to create a coreboot image, a bootfile image, or an entire OS-9 ROM Image. The wizard can also be used to modify an existing image. The Configuration Wizard is automatically installed on your host PC during the OS-9 installation process.
### Starting the Configuration Wizard

**Step 1.** From the Windows desktop, select `Start -> RadiSys -> Microware OS-9 for <product> -> Configuration Wizard`. You should see the following opening screen:

#### Figure 1-2 Configuration Wizard Opening Screen

![Configuration Wizard Opening Screen](image)

**Step 2.** Select your target board from the **Select a board** pull-down menu.

**Step 3.** Select the **Create new configuration** radio button from the **Select a configuration** menu and type in the name you want to give your ROM image in the supplied text box. This names your new configuration, which can later be accessed by selecting the **Use existing configuration** pull down menu.
Step 4. Select the **Advanced Mode** radio button from the **Choose Wizard Mode** field and click **OK**. The Wizard’s main window is displayed. This is the dialog from which you will proceed to build your image. An example is shown in **Figure 1-3**.

**Figure 1-3  Configuration Wizard Main Window**
Configuring Coreboot Options

Most of the default options for the configuration of the coreboot are correct. There are a few functions, however, such as Ethernet, that need additional information in order to be configured correctly. To configure the coreboot options as necessary, complete the following steps:

Step 1. From the menu bar, select Configure -> Coreboot -> Main Configuration.

Step 2. Click on the Debugger tab. Make sure Ethernet is selected in the Remote Debug Connection area and Remote is selected in the Select Debugger area. Remote debugging is enabled so that system-state debugging can be performed in Hawk.

Step 3. Click the Ethernet tab and enter the Ethernet address information in the address text boxes. For most situations you will need to fill out the following information:

- IP address
- IP broadcast
- IP gateway
- subnet mask

If you are uncertain of the values for these text boxes, contact your system administrator.

Step 4. Click OK to close the window.
Configuring Bootfile Options

Most of the default options for the configuration of the bootfile are correct. There are a few functions, however, such as Ethernet, that need additional information in order to be configured correctly. To configure the bootfile options as necessary, complete the following steps:

Step 1. If you want to use the target board across a network, you will need to configure the Ethernet settings within the Configuration Wizard. To do this, select Configure -> Bootfile -> Network Configuration from the Wizard’s main menu.
Step 2. From the **Network Configuration** dialog, select the **Interface Configuration** tab. From here you can select and enable the interface. For example, you can select the appropriate Ethernet card from the list of options on the left and specify whether you would like to enable IPv4 or IPv6 addressing. **Figure 1-4** shows an example of the **Interface Configuration** tab.

**Figure 1-4** Bootfile -> Network Configuration -> Interface Configuration

To learn more about IPv4 and IPv6 functionalities, refer to the **Using LAN Communications** manual, included with this product CD.
Installing and Configuring OS-9®

For More Information
Contact your system administrator if you do not know the network values for your board.

Step 3. Click on the **SoftStax® Setup** tab, and select **Enable SoftStax**.

Step 4. Click **OK** to close the dialog box.

Step 5. Select **Configure -> Bootfile -> Disk Configuration** from the menu and verify that the default settings in the dialog box are acceptable.

Step 6. Select **Configure -> Build Image** from the menu to display the **Master Builder** window.

Step 7. Select the following check boxes as appropriate:
- SoftStax® (SPF) Support
- User State Debugging Modules
  In addition, if you are using a RAM disk, select **Disk Support** and **Disk Utilities**.

Step 8. Click **Coreboot + Bootfile** and then click **Build**. This builds the ROM image that can be burned into flash memory. The name of the file containing the ROM image is `rom.S`. It is in the Motorola S-record format. The file `rom.s` is located in the following directory:

    mwos\OS9000\MIPS32\PORTS\IDT_79E355\BOOTS\INSTALL\PORTBOOT

(The directory above should have been specified as the outgoing directory when the TFTP server was initially set up.)

Step 9. Click **Finish** and then select **File -> Save Settings** to save the configuration.

Step 10. Select **File -> Exit** to exit the Configuration Wizard.
Transferring the ROM Image to the Target

The Hitachi Debug Monitor will be used to transfer the OS-9 ROM image you created in the Building the OS-9 ROM Image section to the HS8001 board and program it into flash. Complete the following steps to transfer the image to the board:

Step 1. From the Hitachi Debug Monitor, type the `ld` command. The Monitor program should echo the following text:

```
Please load from host.
```

Step 2. From HyperTerminal, select Transfer -> Send Text File. Browse to the `rom.S` file and select OK. The file should now download to the HS8001 board.

Step 3. After the ROM file has completed downloading, enter the following commands in the Hitachi Debug Monitor to program it into flash:

```
pf 80000000 0
pf 80040000 1
pf 80080000 2
pf 800c0000 3
pf 80100000 4
pf 80140000 5
pf 80180000 6
pf 801c0000 7
```

Each command will program 256K of flash. Thus, the preceeding commands will program a ROM image that is 2MB.
Setting the Switches to Boot OS-9

The following switches will need to be changed to boot OS-9 directly:

**Note**
Be sure to power off before adjusting these switches.

- SW 10 and SW 11 should be turned to 1.
- SW 28 should be turned to 0.

**Note**
The switches listed above are labeled both in Figure 1-1 and on your HS8001 board.
Optional Procedures

The following sections detail procedures you may perform once you have installed and configured OS-9.

Using OS-9 to Program the Flash

After you have successfully booted the board with OS-9, you can use the `pflash` command to program the flash with an updated bootfile. Below is a list of steps that will show you how to download a file to the HS8001 board running OS-9, and how to use the `pflash` command to program the bootfile into flash.

Step 1. Type `chd /r1` on the command line for the target. This command initiates a large RAM disk that will hold the bootfile.

Step 2. Use FTP to download the bootfile to the `/r1` ram disk.

Step 3. Type `pflash -f=bootfile -un` to program the flash.

Note

If you are programming a ROM image into flash instead of a bootfile, use the following command in place of `pflash -f=bootfile -un`.

`pflash -f=rom -un -ri`
Chapter 2: Board Specific Reference

This chapter contains porting information specific to the HS8001 board. It includes the following sections:

- The Fastboot Enhancement
- OS-9 Vector Mappings
The Fastboot Enhancement

The Fastboot enhancements to OS-9 were added to address the needs of embedded systems that require faster system bootstrap performance. The Fastboot concept exists to inform OS-9 that the defined configuration is static and valid. This eliminates the dynamic search OS-9 usually performs during the bootstrap process. It also allows the system to perform for a minimal amount of runtime configuration. As a result, a significant increase in bootstrap speed is achieved.

Overview

The Fastboot enhancement consists of a set of flags that control the bootstrap process. Each flag informs some portion of the bootstrap code of a particular assumption, and that the associated bootstrap functionality should be omitted.

One important feature of the Fastboot enhancement is the ability of the flags to become dynamically altered during the bootstrap process. For example, the bootstrap code might be configured to query dip switch settings, respond to device interrupts, or respond to the presence of specific resources that indicate different bootstrap requirements.

Another important feature of the Fastboot enhancement is its versatility. The enhancement's versatility allows for special considerations under a variety of circumstances. This can be useful in a system in which most resources are known, static, and functional, but whose additional validation is required during bootstrap for a particular instance (such as a resource failure).
Implementation Overview

The Fastboot configuration flags have been implemented as a set of bit fields. One 32-bit field has been dedicated for bootstrap configuration. This four-byte field is contained within a set of data structures shared by the kernel and the ModRom sub-components. Hence, the field is available for modification and inspection by the entire set of system modules (both high-level and low-level).

Currently, there are six-bit flags defined, with eight bits reserved for user-definable bootstrap functionality. The reserved user-definable bits are the high-order eight bits (31-24). This leaves bits available for future enhancements. The currently defined bits and their associated bootstrap functionality are listed in the following sections.

**B_QUICKVAL**

The B_QUICKVAL bit indicates that only the module headers of modules in ROM are to be validated during the memory module search phase. Limiting validation in this manner will omit the CRC check on modules, which may save a considerable amount of time. For example, if a system has many modules in ROM in which access time is typically longer than it is in RAM, omitting the CRC check will drastically decrease the bootstrap time. Furthermore, since it is rare that data corruption will occur in ROM, omitting the CRC check is a safe option.

In addition, the B_OKRAM bit instructs the low-level and high-level systems to accept their respective RAM definitions without verification. Normally, the system probes memory during bootstrap based on the defined RAM parameters. This method allows system designers to specify a possible range of RAM the system will validate upon startup; thus, the system can accommodate varying amounts of RAM. However, in an embedded system (where the RAM limits are usually statically defined and presumed to be functional) there is no need to validate the defined RAM list. Bootstrap time is saved by assuming that the RAM definition is accurate.
**B_OKROM**

The `B_OKROM` bit causes acceptance of the ROM definition without probing for ROM. This configuration option behaves similarly to the `B_OKRAM` option with the exception that it applies to the acceptance of the ROM definition.

**B_1STINIT**

The `B_1STINIT` bit causes acceptance of the first `init` module found during cold-start. By default, the kernel searches the entire ROM list passed up by the ModRom for `init` modules before it takes the `init` module with the highest revision number. Using the `B_1STINIT` in a statically defined system omits the extended `init` module search, which can save a considerable amount of time.

**B_NOIRQMASK**

The `B_NOIRQMASK` bit instructs the entire bootstrap system to not mask interrupts for the duration of the bootstrap process. Normally, the ModRom code and the kernel cold-start mask interrupts for the duration of the system startup. However, in systems with a well-defined interrupt system (systems that are calmed by the `sysinit` hardware initialization code) and a requirement to respond to an installed interrupt handler during startup, this option can be used. Its implementation will prevent the ModRom and kernel cold-start from disabling interrupts. (This is useful in power-sensitive systems that need to respond to "power-failure" oriented interrupts.)

---

**Note**

Some portions of the system may still mask interrupts for short periods during the execution of critical sections.
B_NOPARITY

If the RAM probing operation has not been omitted, the B_NOPARITY bit causes the system to not perform parity initialization of the RAM. Parity initialization occurs during the RAM probe phase. The B_NOPARITY option is useful for systems that either require no parity initialization or only require it for "power-on" reset conditions. Systems that only require parity initialization for initial power-on reset conditions can dynamically use this option to prevent parity initialization for subsequent “non-power-on” reset conditions.

Implementation Details

This section describes the compile-time and runtime methods by which you can control the bootstrap speed of your system.

Compile-time Configuration

The compile-time configuration of the bootstrap is provided by a pre-defined macro, BOOT_CONFIG, which is used to set the initial bit-field values of the bootstrap flags. You can redefine the macro for recompilation to create a new bootstrap configuration. The new overriding value of the macro should be established as a redefinition of the macro in the rom_cnfg.h header file or a macro definition parameter in the compilation command.

The rom_cnfg.h header file is one of the main files used to configure the ModRom system. It contains many of the specific configuration details of the low-level system. Below is an example of how you can redefine the bootstrap configuration of your system using the BOOT_CONFIG macro in the rom_cnfg.h header file:

```
#define BOOT_CONFIG (B_OKRAM + B_OKROM + B_QUICKVAL)
```

Below is an alternate example showing the default definition as a compile switch in the compilation command in the makefile:

```
SPEC_COPTS = -dNEWINFO -dNOPARITYINIT -dBOOT_CONFIG=0x7
```
This redefinition of the \texttt{BOOT\_CONFIG} macro results in a bootstrap method, which accepts the RAM and ROM definitions without verification. It also validates modules solely on the correctness of their module headers.

**Runtime Configuration**

The default bootstrap configuration can be overridden at runtime by changing the \texttt{rinf->os->boot\_config} variable from either a low-level P2 module or from the \texttt{sysinit2()} function of the \texttt{sysinit.c} file. The runtime code can query jumper or other hardware settings to determine which user-defined bootstrap procedure should be used. An example P2 module is shown below.

---

**Note**

If the override is performed in the \texttt{sysinit2()} function, the effect is not realized until after the low-level system memory searches have been performed. This means that any runtime override of the default settings pertaining to the memory search must be done from the code in the P2 module code.

```c
#define NEWINFO
#include <rom.h>
#include <types.h>
#include <const.h>
#include <errno.h>
#include <romerrno.h>
#include <p2lib.h>

error_code p2start(Rominfo rinf, u_char *glbls)
{
    /* if switch or jumper setting is set... */
    if (switch_or_jumper == SET)
    {
        /* force checking of ROM and RAM lists */
        rinf->os->boot_config &= ~(B_OKROM+B_OKRAM);
    }
    return SUCCESS;
}
```

Appendix A: Board Specific Modules

This chapter describes the modules specifically written for the Hitachi HS8001 board. It includes the following sections:

- Low-Level System Modules
- High-Level System Modules
- Common System Modules List
Board Specific Modules

Low-Level System Modules

The following low-level system modules are tailored specifically for the HS8001 board. They are located in the following directory:

MWOS/OS9000/SH5M/PORTS/HS8001/CMDS/BOOTOBS/ROM

cnfgdata contains low-level configuration data

cnfgfunc provides access services to the cnfgdata

commcnfg inits communication port defined in cnfgdata

conscnfg inits console port defined in cnfgdata

initext user-customizable system initialization module

i016550 ROM based serial I/O driver

i01scif ROM based serial I/O driver

lle91c100 Low-level Ethernet ROM driver

portmenu inits booters defined in the cnfgdata

romcore bootstrap code

tmr8001 ROM timer services

usedebug debugger configuration module

ide ROM based IDE driver

pciwalk pci initialization code
The following OS-9 system modules are tailored specifically for the SH-5 HS8001 boards. Unless otherwise specified, each module is located in the following directory:

MWOS/OS9000/Sh5M/PORTS/HS8001/CMDS/BOOTOBS

- **sc16550**: Serial driver for the 16550 UART
- **sc8001**: Serial driver for the SCIF UART
- **sp91c100**: Ethernet driver module
- **tk8001**: System clock module
- **irq8001**: Interrupt handler module
- **rb1003**: RBF IDE driver
- **rtc8001**: Real-time clock driver
- **sc8042k**: PS/2 mouse and keyboard driver
- **gx_cl543**: Graphics driver for GXCL543 PCI card
- **mp_msptr**: Mouse PS/2 protocol module for MAUI®
- **mp_xtkb**: Keyboard PS/2 protocol module for MAUI
## Common System Modules List

The following low-level system modules provide generic services for OS9000 Modular ROM. They are located in the following directory:

```
MWOS/OS9000/SH5M/CMDS/BOOTOBS/ROM
```

<table>
